The requirements of a combustion data acquisition system are to record cylinder pressure data and align it to cylinder volume data. This is achieved by using a triggered acquisition, (acquisition does not begin until TDC is reached), and sampling using an external clock, (one acquisition per clock pulse).

The data stream then moves the data to a conditioning loop, which de-noises and filters the data. Then it transfers the data to a storage (RAW) and processing loop. The real-time processing loop runs necessary calculations for cylinder volume, pressure rise rate, heat release rate, start and end of combustion, mean effective pressure, and cycle-to-cycle variation in the background.
