The finite element method (FEM) is the dominant discretization technique in structural mechanics. The basic concept in the physical interpretation of the FEM is the subdivision of the mathematical model into disjoint (non -overlapping) components of simple geometry called finite elements or elements for short.

How to deal with the model is important in analyzing structure system with finite element method, because the rationality of model has direct relationship with veracity of simulation result. In this paper some simplify modeling methods are expatiated. And an approach is supposed that combine simplifying complex model and rigid-treating sub-component which make model more close to reality.

Finite element modeling (FEM) uses the concept of representing the object by an analytic model consisting of a finite number of elements that are interconnected at a finite number of points called nodes. This collection of nodes and elements forms the finite element mesh. These are the building blocks of the numerical representation of the model.
