Filter Design Basics. A common DSP task is to design a frequency-selective filter to approximate either a desired impulse response or desired frequency response within certain tolerances. The typical procedure is: 1. Specify the desired properties of the filter 2. Determine the coefficients of linear constant-coefficient causal difference equation that meets the specifications 3. Implement the discrete-time system in a particular realization structure.

The actual procedure for designing digital filters has the same fundamental elements as that for analog filters. First, the desired filter responses are characterized, and the filter parameters are then calculated. Characteristics such as amplitude and phase response are derived in the same way.

Simulated GND filters. From left to right: soft edge (1 wide adjustment filter), hard edge (1 narrow adjustment filter), revers (3 adjustment filters) and horizon (4 adjustment filters). Digital filters are more flexible than real ones. You can manipulate the filter in more ways than just reducing the brightness.

The Ultimate Guide to Filters for Landscape Photography

Polarizers cut about two stops of light, and neutral-density filters are available in a variety of densities from one to four stops (filters up to 20 stops are also available). On brighter days, I've often used a polarizer with a two-stop ND filter to slow the shutter speed sufficiently to blur water.

A FIR filter is used to implement almost any type of digital frequency response. Usually these filters are designed with a multiplier, adders and a series of delays to create the output of the filter. The following figure shows the basic FIR filter diagram with N length. The result of delays operates on input samples.
